Chapter 1: Getting started with lodash

Remarks

Lodash is a library of utilities for manipulating and examining objects and arrays.

v4.13.1	2016-05-23

Examples

Setup

Lodash works equally well on both servers (like node.js) and browsers.

node.js with npm

Download with npm from the CLI:

```
npm install lodash
```

Then in your node scripts:

```
var _ = require("lodash");  
  
// use lodash in your program...
```

Download own copy for clientside in website (ie. in the browser)

1. [Download lodash](#) or use a package manager like npm, jspm or bower.
2. Include the script reference in your page with `<script src="lodash.js"></script>`. (Fix the

path if it's not in same directory as the webpage.)

Use lodash in a browser from a CDN

Go to a [CDN site](#) and select the version you want to use. Copy the link and use it for the script reference in your page.

```
<script src="https://cdn.jsdelivr.net/lodash/4.13.1/lodash.min.js"></script>
```

4.13.1 is current version at time of writing

Read [Getting started with lodash online](#): <https://riptutorial.com/lodash/topic/2522/getting-started-with-lodash>

Chapter 2: Chaining

Remarks

Implicit chaining with `_(arr1)` and explicit chaining with `_.chain(arr1)` work in similar ways. The examples below show how they differ slightly.

Explicit chaining with `_.chain(...)`

```
var arr1 = [10, 15, 20, 25, 30, 15, 25, 35];

var sumOfUniqueValues = _.chain(arr1)
  .uniq()
  .sum()           // sum returns a single value
  .value();       // which must be unwrapped manually with explicit chaining

// sumOfUniqueValues is now 135
```

Implicit chaining with `_(...)`

```
var arr1 = [10, 15, 20, 25, 30, 15, 25, 35];

var sumOfUniqueValues = _(arr1)
  .uniq()
  .sum();          // sum returns a single value and is automatically unwrapped
                  // with implicit chaining

// sumOfUniqueValues is now 135
```

The two behave differently when ending the chain with an operation that returns a single value: With implicit chaining, the "unwrapping" of the single value is implied. (Thus no need to call `.value().`)

(When the implicit chain ends with a collection value, you'll still need to unwrap the result with `.value().`)

Examples

Chaining

Any lodash collection method has two syntaxes.

Without chaining:

```
var arr1 = [10, 15, 20, 25, 30, 15, 25, 35];

var arr2 = _.filter(arr1, function(item){ return item % 10 === 5 });
```

```
// arr2 now contains [15, 25, 15, 25, 35]

var arr3 = _.uniq(arr2);
// arr3 now contains [15, 25, 35]

var arr4 = _.map(arr3, function(item){ return item + 1 });
// arr4 now contains [16, 26, 36]
```

With chaining:

```
var arr1 = [10, 15, 20, 25, 30, 15, 25, 35];

var arr4 = _(arr1)
  .filter(function(item){ return item % 10 === 5 })
  .uniq()
  .map(function(item){ return item + 1 })
  .value();
// arr4 now contains [16, 26, 36] without creating the intermediate results.
```

The chaining version of this is actually more efficient, since no intermediate results are created. The expressions are evaluated lazily by the call to `.value()` at the end of the chain.

Read Chaining online: <https://riptutorial.com/lodash/topic/2846/chaining>

Chapter 3: Utils

Examples

`_.identity`

This method just returns the first argument.

```
var res1 = _.identity(10, 20);
// res1 now is 10

var res2 = _.identity("hello", "world");
// res2 now is "hello"
```

What does `_.identity` mean in lodash documentation?

This method is used throughout *lodash* documentation instead of `function(x){return x;}` (or ES6 equivalent `x => x`).

It usually means either "no transformation" or when used as a predicate: the truthiness of the value.

Example of `_.identity` in documentation of `_.times`

The `_.times` function takes two arguments. Its expressed like this in the documentation: `var res = _.times(n, [iteratee=_.identity])`

The *iteratee* is used to transform the values as they are iterated over.

The documentation shows that the *iteratee* parameter is optional, and if it is omitted it will have the default value of `_.identity`, **which in this case means "no transformation"**

```
var res = _.times(5);          // returns [0, 1, 2, 3, 4]

// means the same as:
var res = _.times(5, _.identity);

// which again does the same as:
var res = _.times(5, function(x){ return x; });

// or with the ES6 arrow syntax:
var res = _.times(5, x => x);
```

Example of `_.identity` in documentation of `_.findKey` and

`_.findLastKey`

The `_.findKey` and `_.findLastKey` functions takes two arguments. Its expressed like this in the documentation: `_.findKey(object, [predicate=_.identity])` and `_.findLastKey(object, [predicate=_.identity])`

This again means that the second parameter is optional, and if it is omitted it will have the default value of `_.identity`, **which in this case means the first (or last) of "anything that is truthy"**

```
var p = {
  name: "Peter Pan",
  age: "Not yet a grownup",
  location: "Neverland"
};

var res1 = _.findKey(p);           // returns "name"
var res2 = _.findLastKey(p);      // returns "location"

// means the same as:
var res1 = _.findKey(p, _.identity);
var res2 = _.findLastKey(p, _.identity);

// which again means the same as:
var res1 = _.findKey(p, function(x) { return x; });
var res2 = _.findLastKey(p, function(x) { return x; });

// or with ES6 arrow syntax:
var res1 = _.findKey(p, x => x);
var res2 = _.findKey(p, x => x);
```

Read Utils online: <https://riptutorial.com/lodash/topic/3192/Utils>

Chapter 4: Working with Lists and Arrays

Syntax

- `_.map(collection, Function) => newCollection`
- `_.filter(collection, Predicate) => newCollection`
- `_.some(collection, Predicate) => true or false`
- `_.reduce(collection, BiFunction, seed) => accumulated value`

Parameters

Parameter	Meaning
Collection	An iterable group of elements. This can be an array or an object.
Function	A function that takes 1 input, and returns one output.
BiFunction	A function that takes 2 inputs, and returns one output.
Predicate	A function that takes 1 input, and returns a boolean value.
seed	The initial value for a reduction operation. When this is left out, the first element of the collection is used instead.

Examples

Use `_.map` to Transform a List

`_.map` is useful for changing a list into a different list in a purely declarative way. Rather than using imperative techniques like a `while` or `for` loop in javascript, you can just specify how you want to manipulate an element of a list and

Use `_.map` to make a new list transformed by the function you provide.

Let's say we want to square all the numbers in a list. First we'll create a list using the `_.range` function:

```
var a = _.range(10); // [ 0, 1, 2, 3, 4, 5, 6, 7, 8, 9 ]
```

Now we'll create a list of squares by using `_.map`:

```
var b = _.map(a, function(e){ return e * e; });  
// b is now [ 0, 1, 4, 9, 16, 25, 36, 49, 64, 81 ]
```

_.filter

Filtering a list down to only the elements we want to do. Lodash provides a function called `_.filter` filters elements based on the predicate function you provide. A predicate is a function that takes data in and returns either true or false.

Let's look at how we'd get just the even numbers from a list of the numbers 0 through 9:

```
var numbers = _.range(0,10);      // [0, 1, 2, 3, 4, 5, 6, 7, 8, 9]

var evenNumbers = _.filter(numbers, function(e){ return e % 2 == 0; });
// evenNumbers is now [ 0, 2, 4, 6, 8 ]
```

_.some

We can assert some predicate over a collection using `_.some` to check if there is at least one member of a collection that meets some criteria. This is great when writing business logic to assert certain conditions on a group of objects. For example, let's say you wanted to make sure at least one person in a group had a driver's license before it was possible for that group to go on a road trip. We make no guarantees on how happy of a group that'll be at the end of the road trip, however.

```
var friends = [
  {
    'name': 'Fred',
    'hasLicense': false
  },
  {
    'name': 'Steve',
    'hasGuitar': true
  },
  {
    'name': 'Mary',
    'hasLicense': true
  },
]

function canGroupDrive(arr){
  return _.some(arr, function(e){ return e.hasLicense; });
}

canGroupDrive(friends);    // returns true
```

_.reduce

Reducing a list to a single value is easy when you have `_.reduce`. Let's say we wanted to see if a group of people could afford a cab ride. We'd want to look at all the money they have together as a group, which means we'd want to reduce a list of objects to a single value, in this case the sum of the money they have.

```
var friends = [
  {
```

```
    'name': 'Alice',
    'money': 10
  },
  {
    'name': 'Bob',
    'money': 3
  },
  {
    'name': 'Clyde',
    'money': 8
  },
]

var totalMoney = function(arr) {
  return _.reduce(
    arr,
    function(accumulated, e) {
      return accumulated + e.money;
    },
    0
  );
}

function canAffordCab(arr) {
  return 18 < totalMoney(arr);
}

canAffordCab(friends); // returns true
```

Read [Working with Lists and Arrays](https://riptutorial.com/lodash/topic/3160/working-with-lists-and-arrays) online: <https://riptutorial.com/lodash/topic/3160/working-with-lists-and-arrays>

Chapter 5: Working with objects

Examples

.has

Determine if an object has (or contains) a key. If the key to search for is expressed as a path (with dot notation) it will traverse nested object structures to determine if the key exists.

```
var obj = {
  a: 2,
  b: 3,
  c: {
    dd:40,
    ee:{
      fff:500
    }
  }
};

var res1 = _.has(obj, "a");           // true
var res2 = _.has(obj, "a.b");        // false
var res3 = _.has(obj, "c");          // true
var res4 = _.has(obj, "c.ee");        // true
var res5 = _.has(obj, "c.fff");      // false
var res6 = _.has(obj, "c.dd.fff");   // false
var res7 = _.has(obj, "c.ee.fff");   // true
```

Arrays can be used to split up parts of the path instead of strings

```
var res8 = _.has(obj, ["a", "b"]);    // false, same as res2
var res9 = _.has(obj, ["c", "ee"]);   // true, same as res4
```

Note

`_.has` will only look at the direct properties (aka. owned properties) of the object.
